

# Materials for CHEMICAL-LOOPING COMBUSTION (CLC)

Anders Lyngfelt  
Chalmers University  
of Technology  
Göteborg

**CHALMERS**

*2<sup>nd</sup> ICEPE  
Efficient Carbon Capture for Coal Power Plants  
Frankfurt, June 20-22, 2011*

# **CO<sub>2</sub> capture**

- **Main CO<sub>2</sub> capture processes (pre-, post-, oxy-) are all based on gas separation**
- **Gas separation inevitably needs energy**
- **From thermodynamics theoretical minimum energy needed can be derived**
- **Available gas separation processes are still far from this minimum, so there is room for improvement, but ...**
- **Chemical-looping combustion has unique potential as no gas separation is needed**

## Chemical-looping combustion (CLC)

- Oxygen transferred from combustion air to fuel by metal oxide particles
- Inherent CO<sub>2</sub> capture:
  - fuel and combustion air never mixed
  - no active gas separation needed
  - large costs/energy penalties of gas separation avoided
- Potential for real breakthrough in costs of CO<sub>2</sub> capture

**CLC is a *new* principle of fuel conversion**

### **Energy production from fuels**

<b>respiration</b>	<b>~2 000 000 000 BC</b>
<b>fire</b>	<b>~500 000 BC</b>
<b>fuel cell</b>	<b>1839</b>
<b>chemical-looping combustion</b>	<b>2003</b>

## CLC can be used for

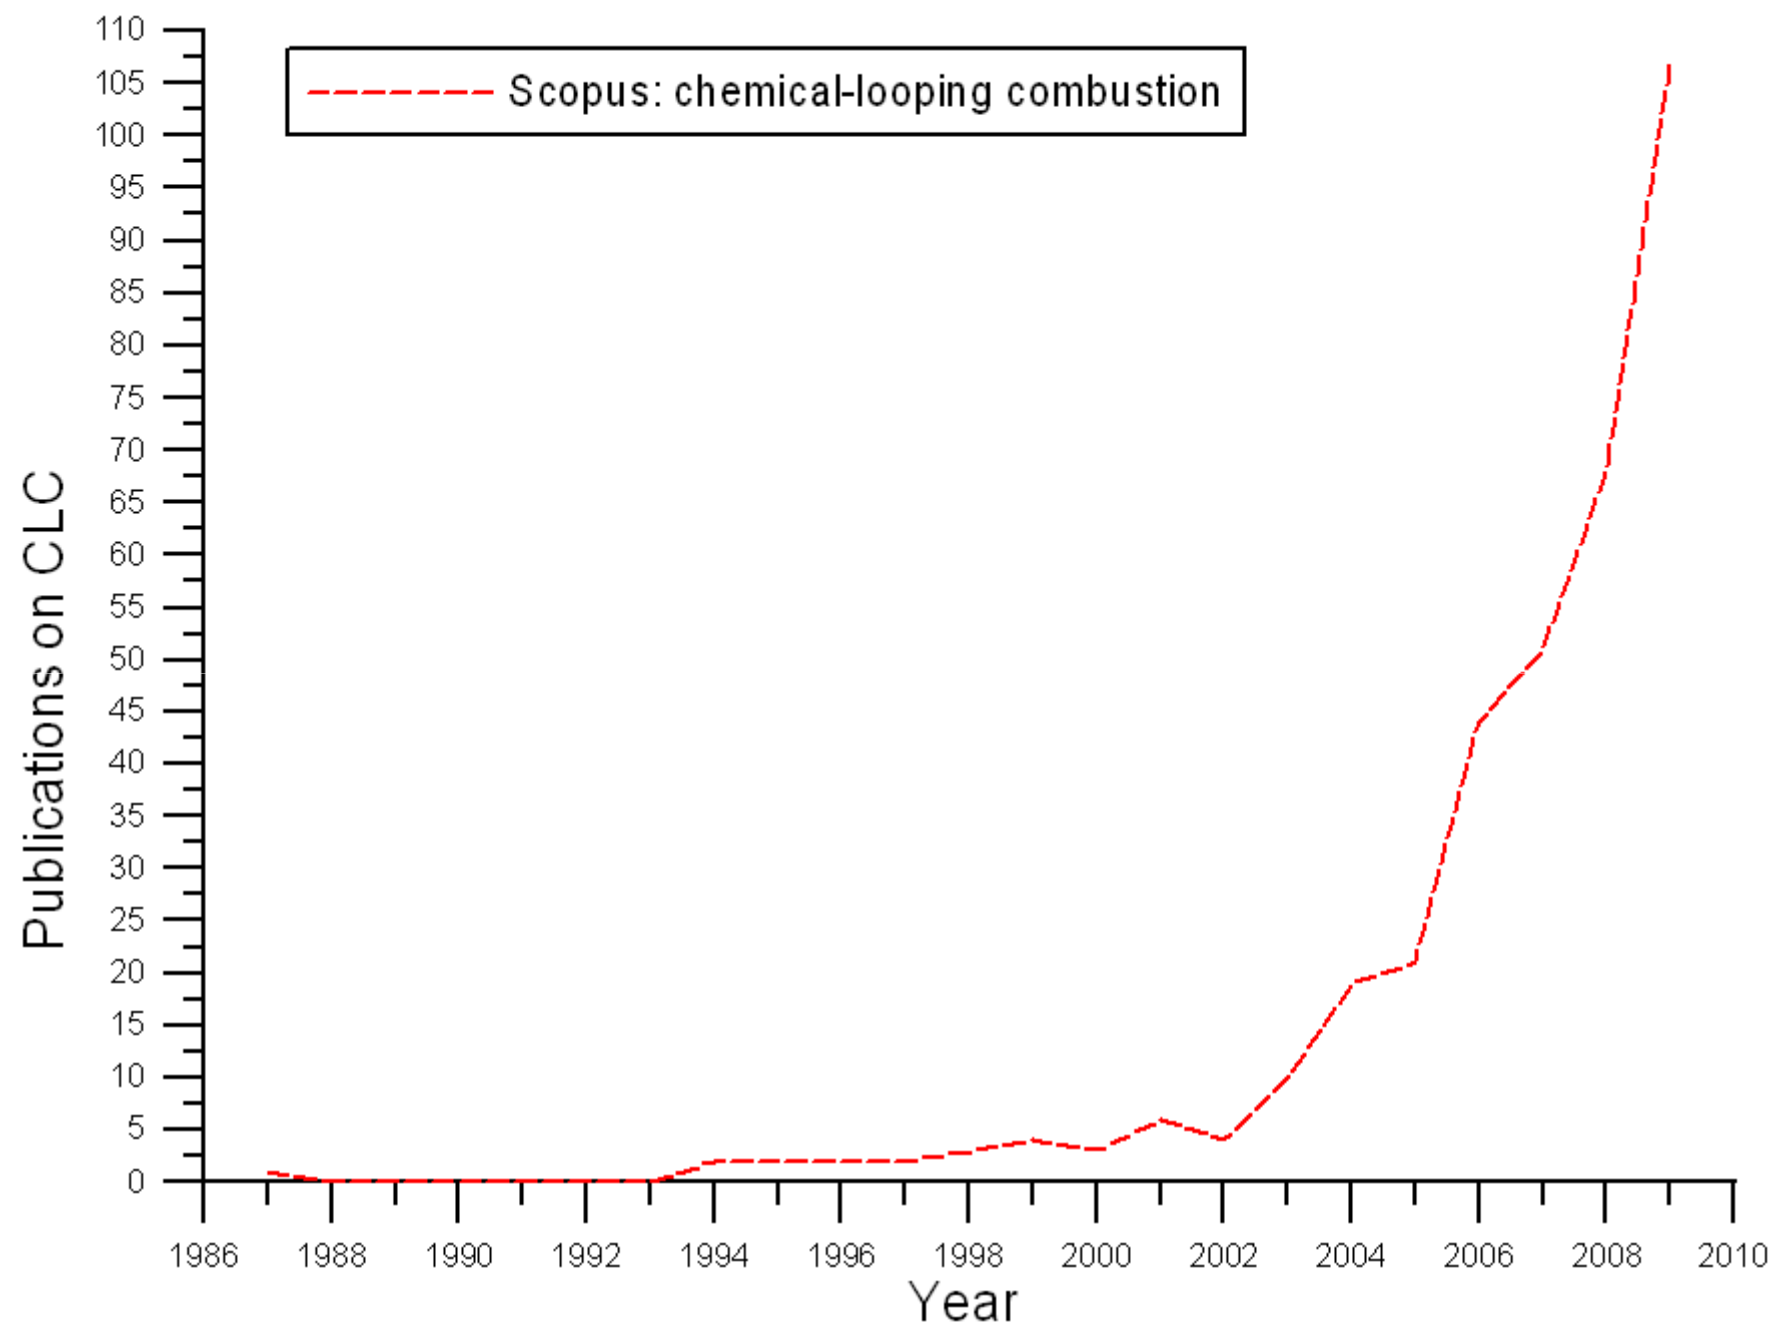

- $\text{CO}_2$ -free combustion of fossil fuels
- $\text{CO}_2$ -negative combustion of biofuels (atmospheric  $\text{CO}_2$  capture)
- Conversion of fossil fuels to  $\text{CO}_2$ -free fuels (below)

### Chemical-looping steam reforming:

- Marriage between conventional steam reforming and chemical-looping combustion
- Converts natural gas to hydrogen and captured  $\text{CO}_2$
- Provides hydrogen, a  $\text{CO}_2$ -free fuel, at 38 €/MWh
- 38 €/MWh less than world market price of crude oil, and appr. 1/3 of price of petrol.

## Chemical-Looping Combustion (CLC) history

- 1954 patented in US for  $\text{CO}_2$  production, forgotten
- 1987/1988/1994 Ishida in Japan introduces the name CLC / starts experimental research / proposes CLC to reduce  $\text{CO}_2$  emissions
- 2003 first successful demonstration 100 h (Chalmers)
- 2006 first operation with solid fuels (Chalmers)
- 2011 >900 oxygen-carrier materials tested in lab
  - >4000 h of operational experience in 14 units worldwide (0.3-140 kW), 30 mtrls

## **Oxygen carrier development.**

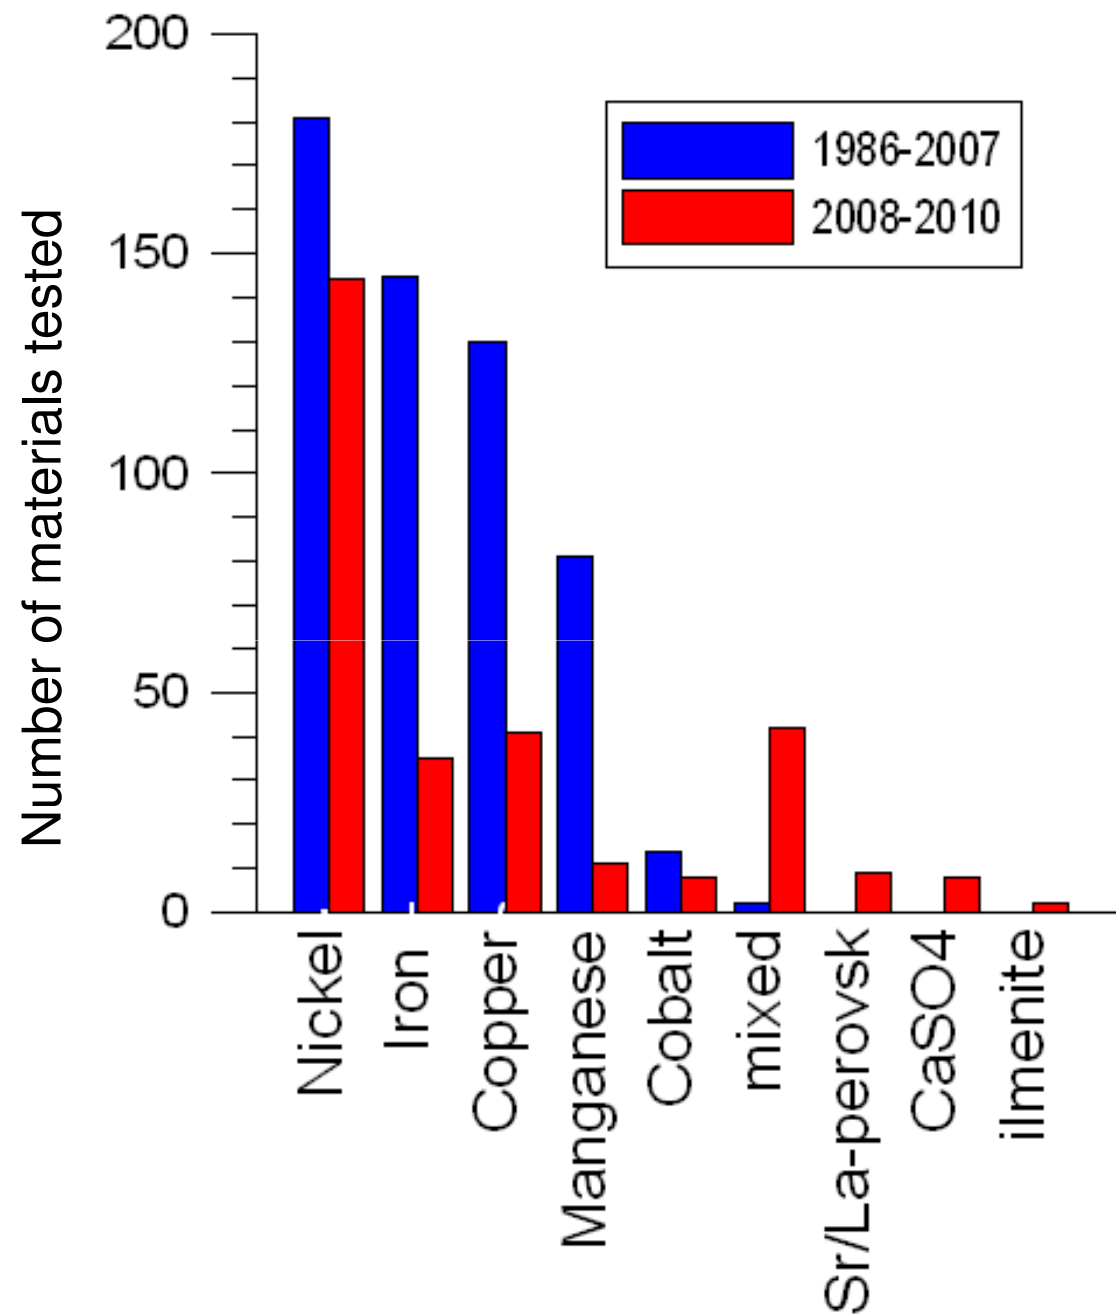

**Mainly oxides of Nickel, Iron, Copper and Manganese  
(NiO, Fe<sub>2</sub>O<sub>3</sub>, CuO, Mn<sub>2</sub>O<sub>3</sub>)**

**Often supported on inert material.**

**Materials mostly tested in laboratory in cyclic  
operation (oxidizing-reducing cycles) in few cycles**

**Majority of materials tested in fixed beds (e.g. in TGA),  
but many hundred mtrls tesded under fluidized  
conditions**

**>30 materials tested in actual operation**

**Phase 1 1986-2007**

**>600 materials**

**Phase 2, 2008-2010**

**>300 materials**

# Reactivity

**Methane (CH<sub>4</sub>) and hydrocarbons**

in order of most reactive to least reactive

**Hydrogen (H<sub>2</sub>)**

most materials very, very reactive

**Carbon monoxide (CO)**

most materials very reactive

Fe<sub>2</sub>O<sub>3</sub> a bit lower though

## COST

Cost Group	Type	Material	Indicative cost, €/ton
Low-cost	Waste mtrls	e.g iron oxides like oxide shell, red mud	0
	Ores	iron ore	50
	-“-	ilmenite (FeTiO <sub>3</sub> )	100
	-“-	manganese ore	300
Medium cost	manufactured mtrls	iron-based	>1000
	-“-	manganese based	>1000
Higher cost	-“-	copper-based	≥3000*
Expensive	-“-	nickel-based	≥20 000*
“Extreme cost”	freeze granulated	nickel-based	500 000

\*Raw mtrl cost

# Health, safety and environmental aspects

## Nickel

- toxic and believed to be carcinogeneuous
- safety measures needed in handling

## Copper and Manganese oxides

- less toxic

## Iron oxide

- edible ?

## Pros and cons for the active oxides

	Fe	Mn	Cu	Ni
Reactivity w $\text{CH}_4$	--	-	+	++
Cost	++	+	-	--
Health				-
Thermodynamics				- <sup>1</sup>
Reaction with $\text{CH}_4$			+ <sup>2</sup>	
Melting point			- <sup>3</sup>	

<sup>1</sup>maximum conversion 99-99.5%

<sup>2</sup>exothermic reaction in fuel reactor

<sup>3</sup>melting point Cu: 1085 C

## Operation in continuous chemical-looping combustors

<b>Location</b>	<b>Unit</b>	<b>Oxides tested</b>	<b>Time</b>	<b>Fuel</b>	<b>Year</b>
<b>Chalmers</b>	<b>10 kW</b>	<b>NiO, Fe<sub>2</sub>O<sub>3</sub></b>	<b>1350</b>	<b>nat. gas</b>	<b>2004</b>

# Chalmers 10 kW CLC, 2003

1 air reactor, 2 cyclone

3 fuel reactor, 4 loop seals

without insulation

## CLC gaseous fuels

- 10 kW tests:
  - 100% capture of CO<sub>2</sub>
  - 98% fuel conversion
  - one mtrl with >1000 h operational experience
  - long lifetime of material demonstrated
- best so far is nickel oxides
- work on-going with other oxygen carriers (better/cheaper)
- ready for scaling up to 1-10 MW<sub>th</sub>

# Solid fuel CLC

**CLC technology very similar to Circulating Fluidized Bed Combustion, commonly used in power plants**

**Potential for a major break-through in cost and energy penalty :**

- **cost 10 €/ton CO<sub>2</sub> (reference 50 €/ton, ??)**
- **3% loss in energy penalty (reference 10%)**

# CLC solid fuels

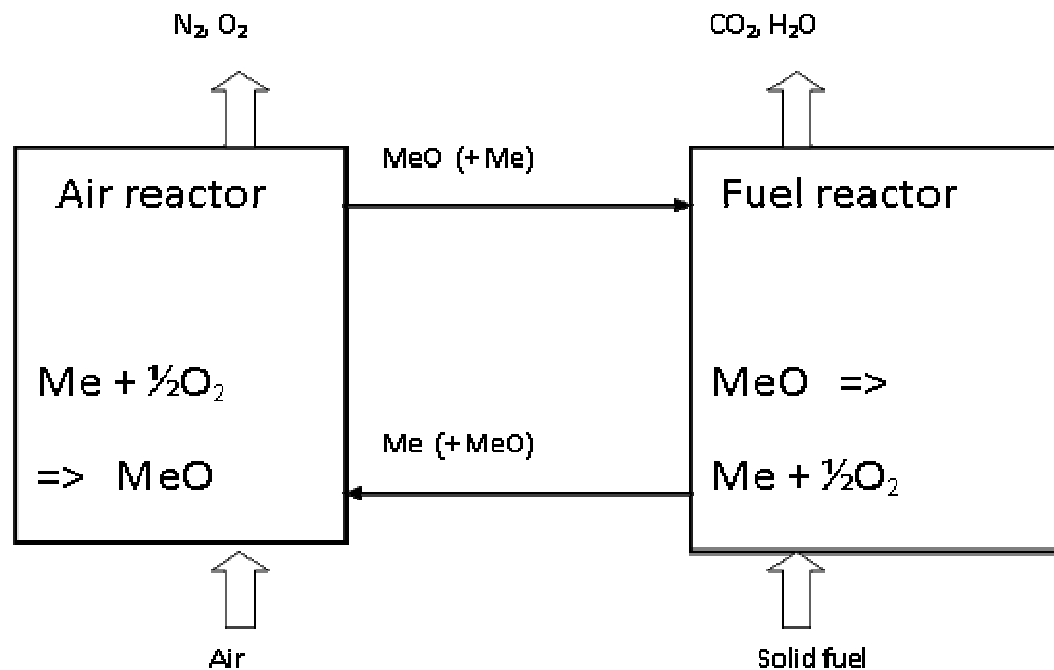

## **Solid fuel CLC, adaptations/challenges**

- cheap oxygen carriers because of fuel ash
  - e.g. ilmenite  $\text{FeTiO}_3$  (natural mineral, 0.1 €/kg)
- bottom bed feeding of fuel (for conversion of volatiles)
- sufficient residence time of solids in fuel reactor (for char conversion)
- carbon stripper, converting/stripping char in solids flow to air reactor
- oxygen polishing, addition of oxygen to gas leaving fuel reactor to reach full gas conversion

## Solid fuel CLC, alternate approach

# Chemical-Looping with Oxygen Uncoupling "CLOU"

uses oxygen carrier that releases gaseous oxygen in fuel reactor

# CLOU

- oxygen carrier with suitable equilibrium partial pressures of  $O_2$
- Example:  $CuO \rightleftharpoons Cu_2O + \frac{1}{2}O_2$ 
  - $p(O_2)_{equilibrium} = 2.5\%$  at 925 C
- Copper oxide releases oxygen extremely fast.  $CuO$  decomposes to  $Cu_2O$  in <30 s. Char conversion rate may increase by 10-100 times, compared to steam gasification.

## Chemical-looping with Oxygen Uncoupling (CLOU)

- ❑ In CLC fuel gases ( $\text{CO}$ ,  $\text{H}_2$ ,  $\text{CH}_4$ ) react with oxygen carrier
- ❑ In CLOU, the oxygen carrier *decomposes* and releases oxygen which reacts directly with the fuel
- ❑ The trick: CLOU materials have an equilibrium partial pressure of  $\text{O}_2$  around 1-5%. Thus, they take up oxygen in the Air Reactor and release oxygen in the Fuel Reactor, because the fuel keeps  $\text{O}_2$  low
- ❑ Oxygen release is a great advantage with solid fuels
- ❑ .... but also with gaseous fuels because it facilitates reaching full gas conversion (in normal CLC very good contact between reacting gas and bed material is needed)

# CLOU

Two types of oxygen carriers for CLOU	
full CLOU	"partial" CLOU
copper oxide materials	manganese oxide combined with iron, calcium, magnesium, silica
extremely fast release of large amounts of oxygen	slower release and smaller amounts of oxygen released... (release of oxygen and direct reaction with reducing gases in parallel)
<ul style="list-style-type: none"><li>• very rapid conversion of char</li><li>• complete conversion of gas</li></ul>	<ul style="list-style-type: none"><li>• complete conversion of gas</li><li>• increased conversion rate of char</li></ul>

## **Focus up to now**

- **gaseous fuels with hydrocarbons:**
  - expensive oxygen carriers with high methane reactivity (Ni)
- **solid fuels:**
  - low cost oxygen carriers with high syngas reactivity (ilmenite)

## **Future development ?**

- **gaseous fuels with hydrocarbons:**
  - oxygen carriers that release oxygen (Cu or combined Mn oxides)
- **solid fuels:**
  - oxygen carriers that release oxygen (Cu or combined Mn oxides)

## Summary

- Major cost of CO<sub>2</sub> capture and storage is capture
- Capture cost CO<sub>2</sub> is caused by *gas separation* (fundamentally and technically well understood, no very fundamental break-throughs likely)
- CLC is a new principle of combustion, where *no gas separation* is needed, because air and fuel are not mixed
- CLC has major potential to reach real *breakthrough* in costs and energy penalty for CO<sub>2</sub> capture
- CLC can be used for combustion of gaseous, liquid and solid fuels – and to produce “CO<sub>2</sub>-free” fuel, hydrogen

## Summary continued

- Oxygen carrier is *key* to low costs and high performance
- Best material depends on fuel/process.
- Trade-off with respect to price, reactivity, estimated lifetime, health/environment.
  - Optimization to select best material will suffer from uncertainties.
  - Thus, best material cannot yet be selected.
  - We need a portfolio of material with different properties/cost
- CLOU mtrls coming next ?

# THANK YOU !

>140 publications on CLC to be found on:
